Answering fundamental questions...

- How to explain particles have mass?
We have theories but need experimental evidence
- What is 96% of the universe made of ?
We can only see 4% of its estimated mass!
- Why isn't there anti-matter
in the universe?
Nature should be symmetric...
- What was the state of matter just
after the « Big Bang » ?
Travelling back to the earliest instants of
the universe would help...

LHC-scale data processing

Event data taking

In 2011 LHC delivered 5.61 fb⁻¹ of p-p collision data

Cross sections and event rates for various processes . as a function of the proton-proton center-of-mass energy.

~300 billion inelastic proton-proton interactions

ATLAS uses a flexible trigger menu to determine which events are interesting enough to record...

ATLAS recorded 1.6 billion events in 2011

The LHC Data Challenge

- The accelerator will run for 20 years
- Experiments *are* producing more than **15 Million Gigabytes** of data each year (about 3 million DVDs – 550 years of movies!)
- LHC data analysis requires a computing power equivalent to **~100,000 of today's fastest PC processors**
- Requires many cooperating computer centres, as CERN can **only provide ~20% of the capacity**

WLCG – what and why?

- A distributed computing infrastructure to provide the production and analysis environments for the LHC experiments
- Managed and operated by a worldwide collaboration between the experiments and the participating computer centres
- The resources are distributed – for funding and sociological reasons
- Our task was to make use of the resources available to us – no matter where they are located

Tier-0 (CERN):

- Data recording
- Initial data reconstruction
- Data distribution

Tier-1 (11 centres):

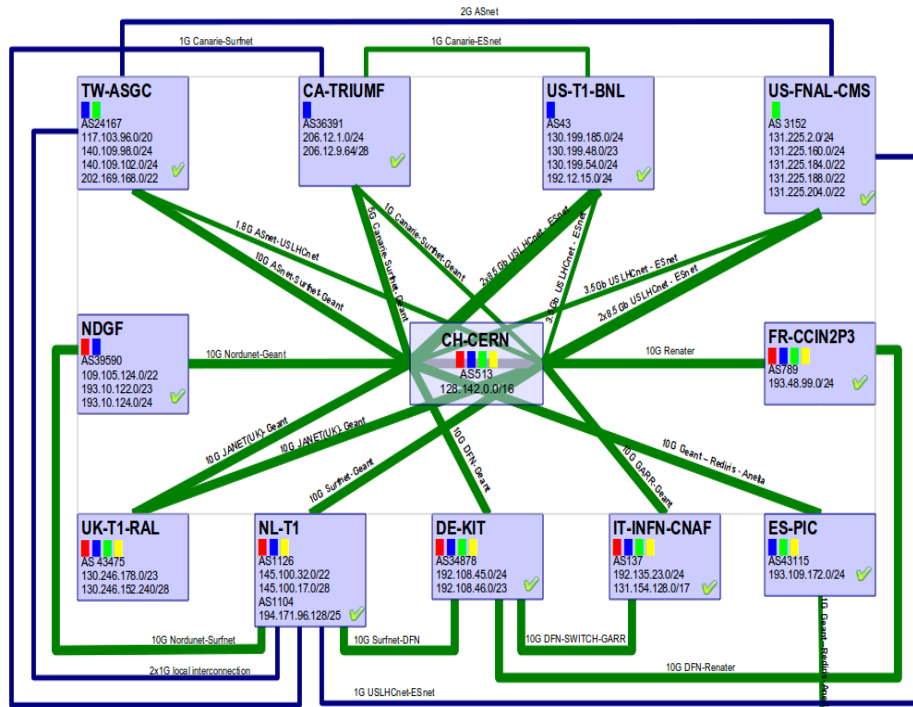

- Permanent storage
- Re-processing
- Analysis

Tier-2 (~130 centres):

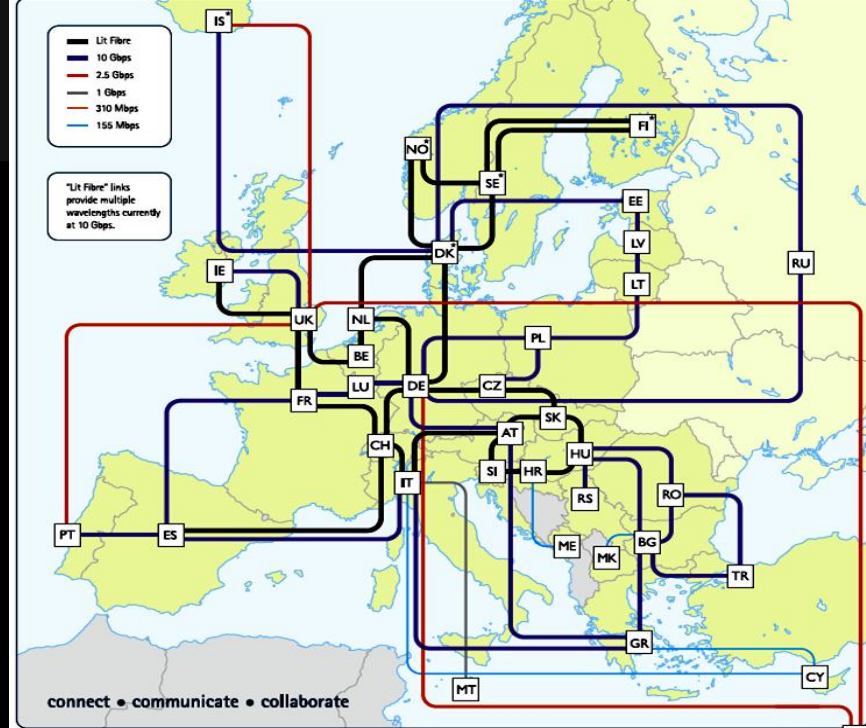

- Simulation
- End-user analysis

Two-pion Bose-Einstein correlations in central Pb-Pb collisions at $\sqrt{s_{NN}} = 2.76$ TeV

The ALICE Collaboration*

Abstract

The first measurement of two-pion Bose-Einstein correlations in central Pb-Pb collisions at $\sqrt{s_{NN}} = 2.76$ TeV at the Large Hadron Collider is presented. We observe a growing trend with energy not only for the longitudinal and the outward but also for the sideward pion source radius. The pion homogeneity volume and the decoupling time are significantly larger than those measured at RHIC.

Study of Jet Shapes in Inclusive Jet Production in pp Collisions at $\sqrt{s} = 7$ TeV using the ATLAS Detector

(The ATLAS Collaboration)

(Submitted: January 8, 2011)

Jet shapes have been measured in inclusive jet production in proton-proton collisions at $\sqrt{s} = 7$ TeV using 3.6×10^6 of data recorded by the ATLAS experiment at the LHC. Jets are reconstructed using the anti- k algorithm with transverse momenta $30 \text{ GeV} < p_T < 400 \text{ GeV}$ and rapidity in the range $|\eta| < 2.4$. The data are corrected for detector effects and compared to several leading-order (LO) matrix elements plus parton shower Monte Carlo predictions, including different sets of parameters based on small fragmentation processes and including event contributions to the final state. The measured jets become narrower with increasing jet transverse momentum and the jet shapes present a moderate jet energy dependence. Within QCD, the data test a variety of perturbative and non-perturbative effects. In particular, the data show sensitivity to the details of the parton shower, fragmentation, and hadronization even visible in the Monte Carlo generation. For an appropriate choice of the parameters used in these models, the data are well described.

I. INTRODUCTION

The study of the jet shapes [1] in proton-proton collisions provides information about the details of the parton-to-jet fragmentation process, leading to collimated flows of particles in the final state. The internal structure of substantially extended jets is usually diluted by the emission of multiple particles from the primary parton, calculable in perturbative QCD (pQCD) [2]. The shape of the jet depends on the type of parton (quark or gluon) that gives rise to jets in the final state [3], and is also sensitive to non-perturbative fragmentation effects and underlying event (UE) contributions from the interaction between proton remnants. A proper modeling of the soft contributions is crucial for the understanding of jet production in hadron-hadron collisions and for the comparison of the jet cross section measurements with pQCD theoretical predictions [4, 5]. In addition, jet shape related observables have been recently proposed [6] to search for new physics in event topologies with highly boosted particles in the final state decaying into multiple jets of particles.

Jet shape measurements have previously been performed in pp [7], e^+p [8], and e^+e^- [9] collisions. In this paper, measurements of differential and integrated jet shapes in proton-proton collisions at $\sqrt{s} = 7$ TeV are presented for the first time. The study uses data collected by the ATLAS experiment corresponding to 3 fb^{-1} of total integrated luminosity. The measurements are corrected for detector effects and compared to several Monte Carlo (MC) predictions based on pQCD leading-order (LO) matrix elements plus parton showers, and including different phenomenological models to describe fragmentation processes and UE contributions.

The paper is organized as follows. The detector is described in the next section. Section 3 discusses the simulation used in the measurements, while Section 4 and Section 5 provide details on jet reconstruction and event selection, respectively. Jet shape observables are defined in Section 6. The procedure used to correct the measurements for detector effects is explained in Section 7, and the study of systematic uncertainties is discussed in Section 8. The jet shape measurements are presented in Section 9. Finally, Section 10 is devoted to summary and conclusions.

II. EXPERIMENTAL SETUP

The ATLAS detector [10] covers nearly the detector, calorimeters, and muon chambers. Its calorimeter use of particular importance.

The ATLAS inner detector has full coverage of a silicon pixel detector, a silicon microstrip detector, and a straw tube detector. High granularity liquid-argon calorimeters in the pseudorapidity range $|\eta| < 3.2$. The hadronic calorimetry in the pseudorapidity range $|\eta| < 3.1$. The ATLAS calorimeters provide both the coverage to $|\eta| < 4.9$.

Minimum bias

ABSTRACT

The first measurements from proton-proton collisions recorded with the ATLAS detector at the LHC are presented. Data were collected in December 2009 using a minimum-bias trigger during collisions at a centre-of-mass energy of 900 GeV. The charged-particle multiplicity, its dependence on transverse momentum and pseudorapidity, and the relationship between mean transverse momentum and charged-particle multiplicity are measured for events with at least one charged particle in the kinematic region $|\eta| < 2.5$ and $p_T > 500$ MeV. The measurements are compared to Monte Carlo models of proton-proton collisions and to results from other experiments at the same centre-of-mass energy. The charged-particle multiplicity per event and unit of pseudorapidity at $\eta = 0$ is measured to be 1.333 ± 0.003 (stat. ± 0.040 (syst.)), which is 5–15% higher than the Monte Carlo models predict.

2010 Published by Elsevier B.V.

1. Introduction

Inclusive charged-particle distributions have been measured in pp and $p\bar{p}$ collisions at a range of different centre-of-mass energy \sqrt{s} . Many of these measurements have been used to constrain phenomenological models of soft-hadronic interactions and to properties at higher centre-of-mass energies. Most of the previous charged-particle multiplicity measurements were obtained by selection data with a double-arm coincidence trigger, thus removing large fractions of diffractive events. The data were then further corrected to remove the remaining single-diffractive component. This selection is referred to as non-single-diffractive (NSD). In some cases, despite charged-particle spectra involves model-dependent corrections for the diffractive components and for effects of the trigger selection with no charged particles within the acceptance of the detector. The measurement presented in this Letter implements a diffractive strategy, which uses a single-arm trigger overlapping with the acceptance of the tracking volume. Results are presented as inclusive distributions, with minimal model-dependence, by requiring one charged particle within the acceptance of the measurement. This Letter reports on a measurement of primary charged particles with a momentum component transverse to the beam direction.

Broader Impact of the LHC Computing Grid

- WLCG has been leveraged on both sides of the Atlantic, to benefit the wider scientific community
 - Europe:
 - Enabling Grids for E-science (EGEE) 2004-2010
 - European Grid Infrastructure (EGI) 2010--
 - USA:
 - Open Science Grid (OSG) 2006-2012 (+ extension?)
- Many scientific applications →

...

A distributed computing infrastructure to provide the production and analysis environments for the LHC experiments

- A collaboration
 - The resources are distributed and provided “in-kind”
- A service
 - Managed and operated by a worldwide collaboration between the experiments and the participating computer centres
- An implementation
 - Today general grid technology with high-energy physics specific higher-level services

Need to evolve the implementation while preserving the collaboration and the service

Physical resources: CPU, Disk, Tape, Networks

Making what we have today more sustainable is a challenge

- Data issues
 - Data management and access
 - How to make reliable and fault tolerant systems
 - Data preservation and open access
- Need to adapt to changing technologies
 - Use of many-core CPUs
 - Global filesystem-like facilities
 - Virtualisation
- Network infrastructure
 - Has proved to be very reliable so invest in networks and make full use of the distributed system

- A science – industry partnership to drive R&D and innovation
- Started in 2002, now in 10th year
- Evaluate state-of-the-art technologies in a challenging environment and improve them
- Test in a research environment today what will be used in industry tomorrow
- Training, Dissemination and Outreach

PARTNERS

CONTRIBUTOR (2012)

A European Cloud Computing Partnership: big science teams up with big business

Strategic Plan

- ▶ Establish multi-tenant, multi-provider cloud infrastructure
- ▶ Identify and adopt policies for trust, security and privacy
- ▶ Create governance structure
- ▶ Define funding schemes

To support the computing capacity needs for the ATLAS experiment

EMBL

Setting up a new service to simplify analysis of large genomes, for a deeper insight into evolution and biodiversity

To create an Earth Observation platform, focusing on earthquake and volcano research

Timeline

Set-up
(2011)

Pilot phase
(2012-2014)

Full-scale
cloud service
market
(2014 ...)

- Select flagships use cases
- Identify service providers
- Define governance model

- Deploy flagships
- Analysis of functionality, performance & financial model
- Success Stories

- More applications
- More services
- More users,
- More service providers

Pilot Phase

Explore / push a series of perceived barriers to Cloud adoption:

- **Security:** Unknown or low compliance and security standards
- **Reliability:** Availability of service for business critical tasks
- **Data privacy:** Moving sensitive data to the Cloud
- **Scalability / Elasticity:** Will the Cloud scale-up to our needs
- **Network performance:** Data transfer bottleneck; QoS
- **Integration:** Hybrid systems with in-house / legacy systems
- **Vendor lock-in:** Vendor dependency once data & applications are transferred to the Cloud
- **Legal concerns:** liability, jurisdiction, intellectual property
- **Transparency:** Clarity of conditions, terms and pricing

What will change in the coming years

- Massive adoption of virtualisation techniques by e-Science centres
 - To reduce operation costs
 - To simplify deployment of applications using images
 - To simplify middleware
- Federated identity system
 - Shibboleth/OpenID style network of trust
- “Grid extensions” added to clouds (first private then public)
 - Federated identity system, support for virtual organisations, etc.
 - Use of commercial cloud services as extensions to in-house resources
- Blurring of the borders between elements of e-infrastructure (networking, grid & supercomputing)
 - Because the users & funding agencies demand it
- Emergence of a data e-infrastructure

Thank you for your attention

Accelerating Science and Innovation
